Fundamentals of RF and Wireless Communications ~~Antenna Basics Wireless~~

An Antenna is a transducer, which converts electrical power into electromagnetic waves and vice versa.
An Antenna can be used either as a transmitting antenna or a receiving antenna. A transmitting antenna
is one, which converts electrical signals into electromagnetic waves and radiates them.

Antenna Theory - Basic Parameters. The basic communication parameters are discussed in this chapter
to have a better idea about the wireless communication using antennas. The wireless communication is
done in the form of waves. Hence, we need to have a look at the properties of waves in the
communications.

Wireless Network Antenna - The Basics of Selecting an Antenna. The selection and installation of access point antenna supplies influence network performance and accessibility. The signal strength or amount of energy radiated from an antenna must do with antenna type and access point transmit specifications.

Antenna used to receive broadcast signals from relaying stations meant for television (TV) sets. The antenna is connected to TV set using cable usually of 75 Ohm. This type of antenna to receive TV signal is designed for VHF and UHF frequencies. There are two main categories of TV antenna viz. Indoor and outdoor.

Some routers will have antennas built in, and sometimes the routers will have a choice of antenna you can attach to the router. There are many specific types of antennas, but three basic types are used most of the time, and will be useful in building a wireless network. The first type of antenna is also the most common--omnidirectional.

The fundamentals of antenna theory requires that the antenna be "impedance matched" to the transmission line or the antenna will not radiate. The concept of VSWR is introduced as a measure of how well matched an antenna is. Bandwidth. The bandwidth of an antenna is the frequency range over which the antenna radiates.

The WiFi signal coming from the antenna is only changed based on the design. More power is done by increasing the radio strength. For example, when a directional antenna dBi rating gets higher its focusing the signal beam into a more narrow path. By narrowing the path in which signal it let out, it allows for more range to be achieved.
